Protease-activated receptor 1 (PAR1) is a member of the G-protein coupled receptors that are proteolytically activated by serine proteases. Recent studies suggest a definite contribution of PAR1 to brain functions, including learning and memory. However, cellular mechanisms by which PAR1 activation influences neuronal activity are not well understood. Here we show that PAR1 activation drives retrograde endocannabinoid signaling and thereby regulates synaptic transmission. In cultured hippocampal neurons from rat, PAR1 activation by thrombin or PAR1-specific peptide agonists transiently suppressed inhibitory transmission at cannabinoid-sensitive, but not cannabinoid-insensitive, synapses. The PAR1-induced suppression of synaptic transmission was accompanied by an increase in paired-pulse ratio, and was blocked by a cannabinoid CB₁ receptor antagonist. The PAR1-induced suppression was blocked by pharmacological inhibition of postsynaptic diacylglycerol lipase (DGL), a key enzyme for biosynthesis of the major endocannabinoid 2-arachidonoylglycerol (2-AG), and was absent in knock-out mice lacking the α isoform of DGL. The PAR1-induced IPSC suppression remained intact under the blockade of metabotropic glutamate receptors and was largely resistant to the treatment that blocked Ca²⁺ elevation in glial cells following PAR1 activation, which excludes the major contribution of glial PAR1 in IPSC suppression. We conclude that activation of neuronal PAR1 triggers retrograde signaling mediated by 2-AG, which activates presynaptic CB₁ receptors and suppresses transmitter release at hippocampal inhibitory synapses.

Introduction

Protease-activated receptors (PARs) are members of seven transmembrane domain G-protein-coupled receptors and consist of four subtypes (PAR1–PAR4) (Ossovskaya and Bunnett, 2004). Activation of PARs is initiated by a unique mechanism that protease cleaves a specific site within extracellular N terminus region of the receptor. This cleavage reveals a new N terminus, which acts as a tethered ligand and then binds and activates the receptor. PARs are abundantly expressed in the brain and have been shown to play various roles in pathophysiological conditions such as neurogenic inflammation, neurodegeneration, and neuroprotection (Ossovskaya and Bunnett, 2004; Luo et al., 2007).

PARs may also contribute to neural functions under physiological conditions. PAR1-deficient mice show defects in passive-avoidance task, cued fear conditioning (Almonte et al., 2007),

and nicotine-induced place preference (Nagai et al., 2006). At cellular levels, PAR1 activation influences synaptic transmission. PAR1 activation potentiated NMDA receptor currents (Gingrich et al., 2000; Mannaioni et al., 2008), induced long-term potentiation (LTP) of excitatory transmission (Maggio et al., 2008) in CA1 pyramidal neurons of hippocampal slices, and enhanced spontaneous release of glutamate onto substantia gelatinosa neurons in spinal cord slices (Fujita et al., 2009). As to the mechanisms, several studies have demonstrated that PAR agonists activate astrocytic PAR1, rather than neuronal PAR1, and induce glutamate release from astrocytes, thereby activating neuronal NMDA receptors in hippocampal acute slices (Lee et al., 2007; Mannaioni et al., 2008; Shigetomi et al., 2008) and hippocampal coculture preparations (Lee et al., 2007). *In situ* hybridization studies suggest that PAR1 is expressed in both astrocytes and neurons, including hippocampal pyramidal and granule cells (Weinstein et al., 1995; Niclou et al., 1998). Our knowledge of the roles of neuronal PAR1 in the regulation of synaptic transmission is, however, rather limited, especially at inhibitory synapses.

Endocannabinoid-mediated retrograde modulation of synaptic transmission plays important roles in various brain functions (Heifets and Castillo, 2009; Kano et al., 2009). Endocannabinoids are released from postsynaptic neurons and retrogradely activate presynaptic CB₁ receptors, which leads to suppression of transmitter release. Endocannabinoid release is induced by postsynaptic depolarization (Kreitzer and Regehr, 2001; Ohno-Shosaku et al., 2001;

Wilson and Nicoll, 2001) and/or activation of several types of $G_{q/11}$ -coupled receptors, including group I metabotropic glutamate receptors (I-mGluRs) (Maejima et al., 2001). Activation of phospholipase $C\beta$ (PLC β) through these receptors produces diacylglycerol (DG), which is then hydrolyzed by DG lipase α (DGL α) and yields the endocannabinoid 2-arachidonoylglycerol (2-AG) (Hashimoto et al., 2005; Maejima et al., 2005; Gao et al., 2010; Tanimura et al., 2010). Importantly, PAR1 activates $G_{q/11}$ protein and stimulates phosphoinositide hydrolysis via PLC β (Ososovskaya and Bunnett, 2004; McLaughlin et al., 2005). Therefore, it is likely that PAR1 activation can drive endocannabinoid signaling. This possibility, however, has never been tested electrophysiologically. In the present study, we used cannabinoid-sensitive inhibitory synapses of cultured hippocampal neurons, and demonstrated for the first time that neuronal PAR1 activation can modulate the synaptic transmission through the endocannabinoid 2-AG signaling.

Materials and Methods

Cell culture. All experiments were performed according to the guidelines laid down by the animal welfare committees of the University of Tokyo, Kanazawa and Niigata Universities. Cultured hippocampal neurons were prepared from newborn Sprague Dawley rats, PAR1 knock-out mice (The Jackson Laboratory) (Connolly et al., 1996), DGL α knock-out mice (Tanimura et al., 2010), and their wild-type littermates, as described previously (Ohno-Shosaku et al., 2001). Male and female animals were used. Briefly, cells were mechanically dissociated from the hippocampi and plated either onto poly-L-ornithine-coated plastic dishes for electrophysiological experiments or low-fluorescence plastic films (Sumilon MS-92132; Sumitomo) for Ca^{2+} imaging. The cultures were kept at 36°C in 5% CO_2 for 12–15 d before use.

Electrophysiology. Double whole-cell recordings were performed from cultured hippocampal neurons using a patch-clamp amplifier (EPC10/2; HEKA Elektronik). Each neuron of a pair was voltage clamped at -80 mV using a patch pipette (3–5 M Ω) filled with the internal solution with the following compositions (in mM): 130 K-gluconate, 15 KCl, 10 HEPES, 0.2 EGTA, 6 MgCl $_2$, 5 Na $_2$ ATP, and 0.2 Na $_2$ GTP (pH 7.3, adjusted with KOH). For the experiments shown in Figure 3E, we used the internal solution with the following compositions for postsynaptic neurons (in mM): 109.6 (for pCa 6) or 121.8 (for pCa 9) K-gluconate, 15 KCl, 10 HEPES, 10 BAPTA, 8.47 (for pCa 6) or 0.0549 (for pCa 9) CaCl $_2$, 5 MgCl $_2$, 5 Na $_2$ ATP, and 0.2 Na $_2$ GTP (pH 7.3, adjusted with KOH) (Hashimoto et al., 2005). One neuron was stimulated by applying positive voltage pulses (to 0 mV, 2 ms) at 0.5 or 0.25 Hz, and IPSCs were measured from the other neuron. The external solution contained the following (in mM): 140 NaCl, 2.5 KCl, 2 CaCl $_2$, 1 MgCl $_2$, 10 HEPES, 10 glucose, and 1 kynurenic acid (pH 7.3, adjusted with NaOH). The recording chamber was perfused with the external solution at a flow rate of 1–3 ml/min. Our culture preparations contain cannabinoid-sensitive and -insensitive inhibitory neurons (Ohno-Shosaku et al., 2001). The cannabinoid sensitivity of IPSCs was determined by triggering depolarization-induced suppression of inhibition (DSI), a form of endocannabinoid-mediated short-term depression (Alger, 2002). We defined cannabinoid-sensitive and -insensitive IPSCs by DSI-positive (>30% of suppression) and DSI-negative (<10% of suppression) IPSCs, respectively. PAR1 activators (thrombin, TFLLR, SFLLRN) were locally applied for 1 min through a capillary tube (250 μ m inner diameter) located near the recorded neurons using a perfusion valve controller (VC-6M; Warner Instruments). All experiments were performed at room temperature.

Ca^{2+} imaging. Hippocampal cultures on the films were incubated with 5 μ M fura-2 AM (Dojindo) at 36°C for 15 min and then transferred to a glass-based dish mounted in the recording chamber and perfused with the external solution (see Electrophysiology, above); 1 mM kynurenic acid was replaced with 0.1 μ M tetrodotoxin. Fluorescence signals for excitation of 340 and 380 nm were measured at 0.2 Hz by using an imaging system (Acquacosmos; Hamamatsu Photonics) mounted on an inverted microscope (IX70; Olympus).

Drugs. TFLLR-NH $_2$, AM251, 3,5-dihydroxyphenylglycine (DHPG), 2-methyl-6-(phenylethynyl)pyridine (MPEP), LY367385, and thapsigargin were purchased from Tocris Bioscience. Thrombin, SFLLRN, and tetrahydrolipstatin (THL) were purchased from Sigma-Aldrich. LY367385 was dissolved in NaOH-containing water as a stock solution. TFLLR, SFLLRN, thrombin, and DHPG were dissolved in water. All other drugs were dissolved in DMSO.

Data analysis. In each experiment, amplitudes of 10 consecutive IPSCs during application of receptor activators were averaged and normalized to the control values before application. Statistical significance was assessed by Student's *t* test or Mann–Whitney *U* test.

Results

Activation of PAR1 induces IPSC suppression

We first examined effects of PAR1 activation on hippocampal IPSCs by using an endogenous PAR activator, thrombin, and two PAR1-selective peptide agonists, TFLLR and SFLLRN. If PAR1 triggers endocannabinoid release, cannabinoid-sensitive IPSCs (see Materials and Methods) would be influenced selectively. As expected, local application of thrombin transiently suppressed cannabinoid-sensitive IPSCs (DSI-positive) (Fig. 1A), but not cannabinoid-insensitive IPSCs (DSI-negative) (Fig. 1B). In the following experiments, we used only the cannabinoid-sensitive IPSCs. In most cases, suppression was recovered gradually from its peak even in the presence of thrombin. When thrombin application was repeated, the second application failed to suppress IPSCs (Fig. 1D,F), which can be explained by receptor desensitization (Kawabata et al., 1999). Similar suppressing effects on cannabinoid-sensitive IPSCs were observed with TFLLR (Fig. 1C) and SFLLRN ($29.0 \pm 6.0\%$ of control). When TFLLR was applied repeatedly, the second application failed to suppress IPSCs (Fig. 1E,F). When TFLLR and thrombin were applied sequentially, IPSCs were suppressed only at the first application regardless of the order (Fig. 1G–I), indicating the involvement of the same receptor. The involvement of PAR1 was further confirmed by the results showing that TFLLR-induced IPSC suppression was absent in PAR1 knock-out mice (Fig. 1J–L). The IPSC suppression induced by thrombin or TFLLR was accompanied by an increase in paired-pulse ratio (Fig. 1M), which is generally used as a marker of presynaptic change. These results indicate that PAR1 activation induces presynaptic suppression of inhibitory transmission at cannabinoid-sensitive synapses.

Endocannabinoid signaling is involved in PAR1-mediated IPSC suppression

We next examined whether the PAR1-driven suppression of IPSCs is mediated by endocannabinoids. The IPSC suppressions induced by thrombin and TFLLR were both abolished by the treatment with AM251 (Fig. 2A,B,E,F). Recent studies have revealed that 2-AG produced by DGL α mediates retrograde synaptic suppression (Gao et al., 2010; Tanimura et al., 2010). Therefore, by using pharmacological and genetic tools, we tested whether the PAR1-driven suppression of IPSCs is dependent on DGL α . Treatment with a DGL inhibitor, THL, completely blocked both thrombin and TFLLR-induced IPSC suppression (Fig. 2C–F). In hippocampal neurons prepared from DGL α knock-out mice, TFLLR failed to suppress IPSCs (Fig. 2G–I). From these results, we conclude that PAR1 activation leads to production and release of 2-AG in a DGL α -dependent manner and induces suppression of GABA release through activation of presynaptic CB $_1$ receptors.

2-AG is produced and released from postsynaptic neurons upon PAR1 activation

We then examined whether 2-AG was produced within postsynaptic neurons upon PAR1 activation, by applying the DGL inhibitor THL to the postsynaptic neurons through patch pipettes. Effectiveness of postsynaptically applied THL was estimated by monitoring DHPG (I-mGluR agonist)-induced and depolarization-induced IPSC suppressions (Fig. 2*J*), both of which were previously demonstrated to be blocked by bath-applied THL in our preparations (Hashimoto et al., 2007b, 2008). When THL was applied postsynaptically, thrombin- and TFLLR-induced IPSC suppressions were reduced by similar degrees to DHPG- and depolarization-induced suppressions (Fig. 2*J*). These results clearly indicate that the IPSC suppression is mediated by 2-AG that is produced and released from postsynaptic neurons upon PAR1 activation.

Neuronal PAR1 is responsible for generation of endocannabinoid signaling

A simple model for PAR1-driven 2-AG release is that PAR1 activation and 2-AG production occur in the same postsynaptic neuron. However, it is also possible that PAR1 activation and 2-AG production occur in separate cells. Recent studies have demonstrated that astrocytes are able to release several gliotransmitters, including glutamate, when cytosolic Ca^{2+} concentration is elevated (Perea et al., 2009). Therefore, it is possible that activation of astrocytic PAR1 causes Ca^{2+} elevation and thereby induces glutamate release, which then activates neuronal I-mGluRs (mGluR1 and/or mGluR5) and initiates 2-AG production through I-mGluR-PLC β -DGL α pathway within the postsynaptic neuron. To test this possibility, effects of combined treatment with the mGluR1 antagonist LY367385 and the mGluR5 antagonist MPEP on PAR1-driven IPSC suppression were examined. This treatment blocked the IPSC suppression induced by the I-mGluR agonist DHPG, but failed to block thrombin- and TFLLR-induced suppressions of IPSCs (Fig. 3*A*).

To test whether gliotransmitters other than glutamate are involved, we treated culture preparations with thapsigargin to deplete Ca^{2+} stores, which is expected to block Ca^{2+} elevation and gliotransmitter release (Mothet et al., 2005). We confirmed that Ca^{2+} transients triggered by TFLLR application were completely blocked in thapsigargin-treated astrocytes (Fig. 3*B,C*). This treatment attenuated the TFLLR-induced suppression of IPSCs, but left a

Figure 1. All data are presented as mean $\pm$ SEM.

Figure 2. Involvement of endocannabinoid signaling in PAR1-induced IPSC suppression. **A–D**, Representative data showing effects of AM251 (0.3 μ M; **A, B**) and THL (5 μ M; **C, D**) on IPSC suppression induced by thrombin (1 U/ml) or TFLLR (10 μ M). Representative IPSC traces acquired before (left) and during (right) application of thrombin or TFLLR are shown in insets. **E, F**, Summary graph showing normalized IPSC amplitudes during application of thrombin (**E**) or TFLLR (**F**) in the presence of AM251 and THL. **G–I**, TFLLR-induced IPSC suppression is absent in DGL α -knock-out (KO) mice. Data are illustrated similarly to Figure 1 *J–L*. **J**, Intracellular application of THL (10 μ M) to a postsynaptic neuron greatly reduced IPSC suppressions by thrombin (1 U/ml), TFLLR (10 μ M), DHPG (20 μ M), and postsynaptic depolarization (5 s) to the similar extents. Filled and open columns represent normalized IPSC amplitudes for control and THL-injected neurons. Numbers in parentheses represent the number of tested cells. WT, Wild-type. ** $p < 0.01$, *** $p < 0.001$. All data are presented as mean $\pm$ SEM.

large part of suppression intact (Fig. 3D). This thapsigargin-resistant component of IPSC suppression should be independent of gliotransmitters, and thus dependent on neuronal PAR1 rather than astrocytic PAR1. As to the thapsigargin-sensitive component, there are two possibilities. This component may be dependent on astrocytic PAR1 and mediated by gliotransmitters. Alternatively, this component may also be dependent on neuronal PAR1, but sensitive

Figure 3. Neuronal PAR1, rather than glial PAR1, is responsible for generation of 2-AG signaling. **A**, Normalized IPSC amplitudes during application of thrombin (1 U/ml), TFLLR (10 μ M), and DHPG (20 μ M) in the presence (open columns) or absence (filled columns) of a mixture of MPEP (5 μ M) and LY367385 (100 μ M). **B, C**, Representative data (**B**) and summary graph (**C**) showing complete suppression of TFLLR-induced Ca^{2+} elevation in glial cells by thapsigargin (1 μ M). **D**, Normalized IPSC amplitudes during application of TFLLR (10 μ M) after treatment with thapsigargin (1 μ M) for 1 h (open column). The control data without thapsigargin-treatment (filled column) (see Fig. 2F) are shown for comparison. **E**, TFLLR-induced IPSC suppression was dependent on postsynaptic Ca^{2+} concentration. After treatment with thapsigargin (1 μ M, 1 h), TFLLR (10 μ M) was applied to the postsynaptic neurons dialyzed with two different pipette solutions, pCa 6 ($n = 7$) and pCa 9 ($n = 8$). Results from nontreated neurons (Fig. 1C) were superimposed (gray triangles). Numbers in parentheses represent the number of tested cells. * $p < 0.05$, *** $p < 0.001$. All data are presented as mean $\pm$ SEM. n.s., Not significant.

to thapsigargin, because neuronal PAR1 activation induces local Ca^{2+} elevation, which can enhance 2-AG production. The endocannabinoid release driven by $G_{q/11}$ -coupled receptors such as I-mGluR and M_1/M_3 receptors has been demonstrated to be dependent on basal Ca^{2+} concentration and enhanced by postsynaptic Ca^{2+} elevation (Hashimoto et al., 2007a). To examine the Ca^{2+} dependence of PAR1-driven 2-AG release, we dialyzed thapsigargin-treated postsynaptic neurons with either pCa 6 or pCa 9 pipette solution (Hashimoto et al., 2005). The TFLLR-induced IPSC suppression was more prominent in the neurons filled with the pCa 6 solution (Fig. 3E). Thus, the thapsigargin-sensitive component of IPSC suppression is likely to include a neuronal PAR1-dependent component. Together, we concluded that a large component, if not all, of 2-AG release was gliotransmitter-independent and neuronal PAR1-dependent.

Discussion

In this study, we have shown, for the first time, that activation of neuronal PAR1 triggers retrograde 2-AG signaling. This PAR1-driven 2-AG signaling leads to suppression of inhibitory synaptic transmission through presynaptic CB_1 receptors in hippocampal neurons. Because PAR1 and CB_1 are distributed widely in the brain, this PAR1- CB_1 coupling is likely to be functional and to contribute to synaptic modulation throughout the brain, simi-

larly to other endocannabinoid-producing receptors including glutamate (I-mGluR), acetylcholine (M_1/M_3), serotonin (5-HT₂), oxytocin, orexin, and glucocorticoid receptors (Maejima et al., 2001; Kim et al., 2002; Haj-Dahmane and Shen, 2005; Best and Regehr, 2008; Kano et al., 2009).

Our results are supported by previous biochemical, anatomical, and Ca^{2+} -imaging studies. A biochemical study showed effects of thrombin on endocannabinoid levels in dorsal root ganglia (DRG) neurons (Vellani et al., 2008). The treatment of rat cultured DRG neurons with 100 nM thrombin elevated the levels of two major endocannabinoids, anandamide and 2-AG. The authors proposed a model in which PAR-PLC β -DGL α pathways mediate thrombin-induced 2-AG production. It has been reported that rat cultured hippocampal neurons exhibit PAR1-immunoreactivity and expression of mRNA (Gorbacheva et al., 2009). Furthermore, the study using Ca^{2+} -imaging has demonstrated the presence of functional PAR1 in cultured hippocampal neurons (Bushell et al., 2006). Because neuronal PAR1 expression has been also reported in brain slices (Weinstein et al., 1995; Niclou et al., 1998), we expect that neuronal PAR1-driven 2-AG signaling is functional also *in vivo*. However, cultured neurons could be different from the neurons *in vivo* in some aspects and we cannot exclude the possibility that PAR1 is upregulated under culture conditions. Further studies with slice preparations are necessary to understand the physiological significance of the PAR1-driven 2-AG signaling.

Previous studies with hippocampal slices demonstrated that PAR1 activation positively regulates neuronal excitatory synaptic activity (Gingrich et al., 2000; Lee et al., 2007; Maggio et al., 2008; Mannaioni et al., 2008). To the best of our knowledge, there are no studies reporting PAR1-induced suppression of excitatory transmission. Considering that hippocampal excitatory transmission is much less sensitive to cannabinoids (Ohno-Shosaku et al., 2002), it is possible that 2-AG signaling triggered by PAR1 activation is too weak to cause a detectable change in the excitatory transmission. We showed that PAR1-driven 2-AG signaling was independent of I-mGluR, indicating that PAR1-induced glutamate release from astrocytes (Lee et al., 2007) contributes little to 2-AG generation. The amount of glutamate released from astrocytes might be too small to trigger 2-AG synthesis in neurons. It is also possible that glia–neuron crosstalk was disconnected in our culture preparations, although a previous study clearly demonstrated that the crosstalk was intact even in culture (Lee et al., 2007).

In the hippocampus, PAR1 activators could exert opposite actions on excitatory and inhibitory synaptic transmissions. The potentiation of excitation is mediated by astrocytic PAR1 and gliotransmitters (Lee et al., 2007; Mannaioni et al., 2008), and the suppression of inhibition is mediated by neuronal PAR1 and endocannabinoids. If these two pathways are driven simultaneously, the excitatory signal is synergistically potentiated and LTP induction may be facilitated. The finding that PAR1 triggers 2-AG signaling provides a new insight into the roles of PAR1 under not only physiological but also pathological conditions. The endocannabinoid system has also been reported to be associated with neurodegeneration and neuroprotection (Fowler et al., 2010). It will be of great interest to investigate whether PAR1-driven 2-AG signaling contributes to the previously reported roles of PAR1 in the CNS.
