**Cover picture:** Radial glial processes in the developing cerebral cortex of the mouse defined by placement of a fluorescent lipophilic carbocyanine dye (DiI; Molecular Probes) on the ventricular surface. DiI placements in the embryonic cortex and thalamus were combined with immunolabeling for chondroitin sulfate proteoglycans (CSPGs) to demonstrate that thalamocortical axons selectively extend along the CSPG-rich subplate, while cortical efferent axons extend across the subplate, then turn abruptly to run in the upper intermediate zone toward the forming internal capsule. These relationships suggest a role for CSPGs in defining discrete axonal pathways. See Bicknese et al., pp. 3500–3510.

**Erratum:** In “Self-Recognition: A Constraint on the Formation of Electrical Coupling in Neurons,” by P.B. Guthrie, R.E. Lee, V. Rehder, M.F. Schmidt, and S.B. Kater, which appeared in the March 1994 Part II issue, pp. 1477–1485, the current addresses of the authors were incorrectly footnoted. Peter B. Guthrie, Robert E. Lee, and Stanley B. Kater remain at the Program in Neuronal Growth and Development, Department of Anatomy and Neurobiology, Colorado State University. Vincent Rehder is currently at the Department of Biology, Georgia State University, P.O. Box 4010, Atlanta, GA 30302-4010. Marc F. Schmidt is currently at the Division of Biology 216-76, California Institute of Technology, 1201 East California, Pasadena, CA 91125.
