

The Journal of Neuroscience

March 9, 2011 • Volume 31 Number 10 • www.jneurosci.org

Cover legend: Primary motor neurons in culture stained with a neurofilament antibody to visualize their highly polarized morphology. Nuclei are stained with DAPI (blue). The spinal muscular disease protein SMN facilitates the subcellular localization and trafficking of RNA-binding proteins and mRNAs along the long axonal processes. For more information, see the article by Fallini et al. in this issue (pages 3914–3925).

Correction: The authors regret omissions in the following articles: “Medial Dorsal Hypothalamus Mediates the Inhibition of Reward Seeking after Extinction”, by Nathan J. Marchant, Teri M. Furlong, and Gavan P. McNally, which appeared on pages 14102–14115 of the October 20, 2010 issue; and “Lateral Hypothalamus Is Required for Context-Induced Reinstatement of Extinguished Reward Seeking” by Nathan J. Marchant, Adam S. Hamlin, and Gavan P. McNally, which appeared on pages 1331–1342 of the February 4, 2009 issue. Some details of the methods were omitted in the published versions of these manuscripts. Food and water were freely available before surgery and during the first 3 d postoperatively. During self-administration and extinction training, rats were allowed 1.5 h access to food and water following daily training sessions. These details do not affect the interpretation or conclusions.
