Cover legend: This image shows that a *rainbow* enhancer restrictively expressed green fluorescent protein in red, green, and blue (RGB) cones in the zebrafish retina. In zebrafish, RGB cones are structurally similar and unite into mirror-symmetric pentamers (G-R-B-R-G) by adhesion. This structural commonality and unity suggests that a set of genes is commonly and restrictively expressed in RGB cones but not in other cells; *rainbow* enhancers may represent a cis-regulatory mechanism that underlies such transcriptional regulation to ultimately define the functions of RGB cones, which largely constitute the beginning of the color vision pathway. To learn more about *rainbow* enhancers, see article by Fang et al. (pages 2834–2848).
